• There is an upper limit to how many parallel processes you can use (Amdahl's law) before the efficiency drops significantly.

・ロト ・ 日 ・ モー・ モー・ うへぐ

• There is an upper limit to how many parallel processes you can use (Amdahl's law) before the efficiency drops significantly.

・ロト ・ 日 ・ モー・ モー・ うへぐ

• QMC can often make use of much larger machines compared with DFT or exact diagonalisation.

- There is an upper limit to how many parallel processes you can use (Amdahl's law) before the efficiency drops significantly.
- QMC can often make use of much larger machines compared with DFT or exact diagonalisation.
- Two of the biggest barriers to improved scaling are load imbalances and communication overhead.

- There is an upper limit to how many parallel processes you can use (Amdahl's law) before the efficiency drops significantly.
- QMC can often make use of much larger machines compared with DFT or exact diagonalisation.
- Two of the biggest barriers to improved scaling are load imbalances and communication overhead.
- The use of non-blocking communications and improved load balancing was successful for CASINO (Gillan, Towler, Alfe) so can we use similar ideas here?

Parallel Strategies

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Parallel Implementation (Booth, Smart, Alavi 2014)

• Distribute list of occupied determinants across all processors.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Parallel Implementation

• Each processor evolves main list and spawn into spawned walker list.

Parallel Implementation

• Communicate spawned array using MPIAlltoAllv.

Parallel Implementation

• Communicate spawned array using MPIAlltoAllv.

• At any point in time we need to know on which processor a given determinant should reside for annihilation to take place.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のへぐ

• At any point in time we need to know on which processor a given determinant should reside for annihilation to take place.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

• Storing a list is not practical.

- At any point in time we need to know on which processor a given determinant should reside for annihilation to take place.
- Storing a list is not practical.
- Distributing according to integer label not likely to succeed.

◆□▶ ◆□▶ ★□▶ ★□▶ ● ● ●

- At any point in time we need to know on which processor a given determinant should reside for annihilation to take place.
- Storing a list is not practical.
- Distributing according to integer label not likely to succeed.

• Use a hash function to randomise procedure somewhat.

うして ふゆう ふほう ふほう ふしつ

- At any point in time we need to know on which processor a given determinant should reside for annihilation to take place.
- Storing a list is not practical.
- Distributing according to integer label not likely to succeed.

$$|\Psi\rangle =$$

- Use a hash function to randomise procedure somewhat.
- Assign determinant to processor as $p = \operatorname{hash}(|D_i\rangle) \operatorname{mod} N_p$, $\operatorname{hash}(x) = a, a \in [0, N_{\max}).$

• Hashing should result in an even distribution of walkers.

- Perfect load balancing would require storage of mapping on every processor.
- Instead look for simple approach which should be good enough.
- Idea: split hash range into M bins and redistribute these bins.

▲□▶ ▲圖▶ ▲国▶ ▲国▶ - 国 - のへで

Procedure:

1. Find processors with populations either above (P_i^d) or below (P_i^r) the ideal average walker population $(N_{\text{av}} \pm \delta)$.

- 2. Sort list of donor bins in increasing order of bin size.
- 3. Redistribute donor bins to receiver processors while $N_w(P_i^d) \ge N_{av} \delta$ and $N_w(P_i^r) \le N_{av} + \delta$.

• Define array $p_{\text{map}}[i] = (0, 1, \dots, N_p, 0, \dots, N_p, \dots)$. So, $P(|D_i\rangle) = p_{\text{map}}[\text{hash}(|D_i\rangle) \text{mod}(N_p \times M)]$

ション ふゆ マ キャット マックシン

• Just modify entries in $p_{\rm map}$ so processors are mapped to new processor in the future.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のへぐ

• Just modify entries in p_{map} so processors are mapped to new processor in the future.

ション ふゆ マ キャット マックシン

• For M = 1 get usual procedure, for $M \to N_{\text{Dets}}$ get 'perfect' load balancing.

• Just modify entries in $p_{\rm map}$ so processors are mapped to new processor in the future.

- For M = 1 get usual procedure, for $M \to N_{\text{Dets}}$ get 'perfect' load balancing.
- Trade off between overhead and improving load balancing. $M \sim 20 100$ is usually good enough.

うして ふゆう ふほう ふほう ふしつ

• Just modify entries in $p_{\rm map}$ so processors are mapped to new processor in the future.

- For M = 1 get usual procedure, for $M \to N_{\text{Dets}}$ get 'perfect' load balancing.
- Trade off between overhead and improving load balancing. $M \sim 20 100$ is usually good enough.

ション ふゆ マ キャット マックシン

• Only need to distribute infrequently after equilibration.

ション ふゆ マ キャット マックシン

• Only need to distribute infrequently after equilibration.

• Another barrier to optimal scaling is the communication overhead which gets worse as the processor count increases.

・ロト ・ 日 ・ モ ト ・ モ ・ うへぐ

• Another barrier to optimal scaling is the communication overhead which gets worse as the processor count increases.

・ロト ・ 日 ・ モ ・ ト ・ モ ・ うへぐ

• Non-blocking communications can potentially mitigate these effects by overlapping computation with communication.

- Another barrier to optimal scaling is the communication overhead which gets worse as the processor count increases.
- Non-blocking communications can potentially mitigate these effects by overlapping computation with communication.
- How can this be achieved in FCIQMC when psips need to annihilate?

- Another barrier to optimal scaling is the communication overhead which gets worse as the processor count increases.
- Non-blocking communications can potentially mitigate these effects by overlapping computation with communication.
- How can this be achieved in FCIQMC when psips need to annihilate?
- Solution: They don't need to annihilate every step once they annihilate at the same point in time (continuous time extension: Spencer, Foulkes).

- Another barrier to optimal scaling is the communication overhead which gets worse as the processor count increases.
- Non-blocking communications can potentially mitigate these effects by overlapping computation with communication.
- How can this be achieved in FCIQMC when psips need to annihilate?
- Solution: They don't need to annihilate every step once they annihilate at the same point in time (continuous time extension: Spencer, Foulkes).

Non-Blocking algorithm

- Evolve main list to $\tau + \Delta \tau$ (receiving spawned walkers in background)
- Complete receive
- \bullet Evolve walkers spawned onto current processor to $\tau+\Delta\tau$

ション ふゆ マ キャット マックシン

- Non-blocking send of walkers to their new processors.
- Annihilate walkers on current processor
