## FCIQMC & CCMC in a nutshell

$$\Psi(\tau) = \hat{C}(\tau)|D_0\rangle$$

$$\hat{C} = \sum_{\mathbf{i}} c_{\mathbf{i}} \hat{a}_{\mathbf{i}}$$

Solve iteratively  $\Psi(\tau + \delta\tau) = e^{-\delta\tau(\hat{H}-S)}\Psi(\tau)$ .

FCIQMC samples both the **propagator** and the wavefunction **representation**.

## FCIQMC & CCMC in a nutshell

$$\Psi(\tau) = \hat{C}(\tau)|D_0\rangle$$

$$\hat{C} = \sum_{\mathbf{i}} c_{\mathbf{i}} \hat{a}_{\mathbf{i}}$$

Solve iteratively  $\Psi(\tau + \delta\tau) = e^{-\delta\tau(\hat{H}-S)}\Psi(\tau)$ .

FCIQMC samples both the **propagator** and the wavefunction **representation**.

CCMC uses a different parameterization of the wavefunction.

$$\Psi(\tau) = e^{\hat{T}(\tau)}|D_0\rangle$$

$$\hat{T} = \sum_{\mathbf{i}} t_{\mathbf{i}} \hat{a}_{\mathbf{i}}$$

$$\Psi(\tau + \delta\tau) = e^{-\delta\tau(\hat{H}-S)}\Psi(\tau)$$

Now we must sample the **propagator**, **exponential**, and **representation**.  $\hat{T}$  is represented by discrete **excips**.

## FCIQMC & CCMC in a nutshell

$$\Psi(\tau) = \hat{C}(\tau)|D_0\rangle$$

$$\hat{C} = \sum_{\mathbf{i}} c_{\mathbf{i}} \hat{a}_{\mathbf{i}}$$

Solve iteratively  $\Psi(\tau + \delta\tau) = e^{-\delta\tau(\hat{H}-S)}\Psi(\tau)$ .

FCIQMC samples both the **propagator** and the wavefunction **representation**.

CCMC uses a different parameterization of the wavefunction.

$$\Psi(\tau) = e^{\hat{T}(\tau)}|D_0\rangle$$

$$\hat{T} = \sum_{\mathbf{i}} t_{\mathbf{i}} \hat{a}_{\mathbf{i}}$$

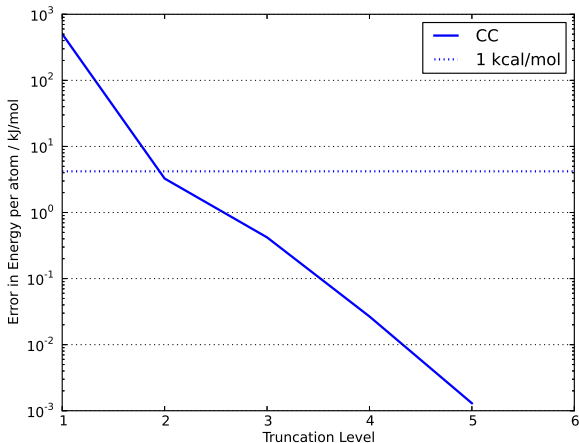

$$\Psi(\tau + \delta\tau) = e^{-\delta\tau(\hat{H}-S)}\Psi(\tau)$$

Now we must sample the **propagator**, **exponential**, and **representation**.  $\hat{T}$  is represented by discrete **excips**.

CC Theories can be truncated size-consistently at excitation levels.

# When do they work?

## FCIQMC

- ▶ Still small systems, but bigger than exact diagonalization.
- ▶ Some systems are easy with low plateau (Hubbard low  $U$ , UEG low  $r_s$ ), others hard (high  $U, r_s$ , alkanes)
- ▶ i-FCIQMC, semi-stochastic, real weights make more tractable.
- ▶ Still have to try a system to find out if it can be investigated.

## CCMC

- ▶ Size-consistent excitation level truncation allows much larger systems to be investigated.
- ▶ Plateaux also vary with system difficulty.
- ▶ Multi-reference systems are much harder.
- ▶ i-CCMC, real weights should all be useful.

# When do they work?

## FCIQMC

- ▶ Still small systems, but bigger than exact diagonalization.
- ▶ Some systems are easy with low plateau (Hubbard low  $U$ , UEG low  $r_s$ ), others hard (high  $U, r_s$ , alkanes)
- ▶ i-FCIQMC, semi-stochastic, real weights make more tractable.
- ▶ Still have to try a system to find out if it can be investigated.

## CCMC

- ▶ Size-consistent excitation level truncation allows much larger systems to be investigated.
- ▶ Plateaux also vary with system difficulty.
- ▶ Multi-reference systems are much harder.
- ▶ i-CCMC, real weights should all be useful.

We would like to know if it's possible to do a calculation without having to try. How can we measure difficulty?

## In Praise of Automation

- ▶ Plateau finding automated at  $N_{\text{ex}}(\tau_{\text{max}})$  where

$$\tau_{\text{max}} = \max_{\tau} \frac{N_{\text{ex}}}{N_0}.$$

- ▶ Error bars come from standard deviation of 10 largest values.
- ▶ Energy analysis automated by fitting form of  $N_{\text{ex}}(\tau)$  and finding equilibrated  $N_{\text{ex}}$ ,  $N_0$ ,  $E_{\text{proj}}$  and  $S$ .

# Finite Electron Gases

- ▶ The Uniform Electron Gas comes in many guises.
- ▶ Most commonly it is expressed in a periodically repeating cell.
- ▶  $r_s$  characterises the density.
- ▶  $\varepsilon_{\text{corr}}(r_s)$  for  $N \rightarrow \infty$  is well-known and used for LDA.
- ▶ Loos and Gill have been concentrating on UEGs in other geometries (ring, sphere, glome ...).
- ▶ These have different  $\varepsilon_{\text{corr}}(r_s)$  which can be used to make an improved density functional.
- ▶ Can we use FCIQMC to calculate  $\varepsilon_{\text{corr}}(r_s)$ ?

# Ringium

- ▶ Electrons confined on a ring radius  $R$ .
- ▶  $r_s = \pi R/n$ .
- ▶ Kinetic Energy is one-dimensional.
- ▶ Coulomb interaction is through-space (i.e.  $1/r_{12}$ ) not around ring.
- ▶ HF orbitals just  $e^{im\phi}$ .

## Ringium basis

Restricted Hartree–Fock orbitals for  $M_L = 0$  are

$$\chi_m(\phi) = e^{2\pi i m \phi} \text{ with } \begin{cases} m \in Z & \text{for odd } N \\ m = \frac{2n+1}{2}, n \in Z & \text{for even } N \end{cases}$$

$M$  indicates the maximum value of  $m$ .

1D Coulomb enforces nodes making ringium is spin-blind.

# Thoughts

- ▶ For 1D and 3D UEG, rapid change of behaviour between easy and hard at  $r_s \approx 1$ .
- ▶ As  $r_s$  increases, both FCIQMC and CCMC reach a constant plateau height.
- ▶ Structure of Hamiltonian dominated by  $r_s^{-1}$  off-diagonal over  $r_s^{-2}$  diagonal.
- ▶ CCMC plateaux usually smaller than FCIQMC's.
- ▶ 3D UEG with FCIQMC/CCMC probably possible.
